Protocol for the Examination of Specimens From Patients With Carcinoma of the Adrenal Gland

Version: 4.2.0.0
Protocol Posting Date: June 2021
CAP Laboratory Accreditation Program Protocol Required Use Date: March 2022

The changes included in this current protocol version affect accreditation requirements. The new deadline for implementing this protocol version is reflected in the above accreditation date.

For accreditation purposes, this protocol should be used for the following procedures AND tumor types:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resection</td>
<td>Adrenalectomy</td>
</tr>
<tr>
<td>Tumor Type</td>
<td>Description</td>
</tr>
<tr>
<td>Adrenal cortical carcinoma</td>
<td>For all age groups with a diagnosis of adrenal cortical carcinoma. This protocol is not designed for adrenal cortical tumors or neoplasms of uncertain malignant potential.</td>
</tr>
</tbody>
</table>

This protocol is NOT required for accreditation purposes for the following:

<table>
<thead>
<tr>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Biopsy (includes needle and incisional biopsies)</td>
</tr>
<tr>
<td>Primary resection specimen with no residual cancer (eg, following neoadjuvant therapy)</td>
</tr>
<tr>
<td>Cytologic specimens</td>
</tr>
</tbody>
</table>

The following tumor types should NOT be reported using this protocol:

<table>
<thead>
<tr>
<th>Tumor Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tumors of the adrenal medulla (eg, pheochromocytoma)</td>
</tr>
<tr>
<td>Pediatric adrenal cortical tumors or neoplasms of uncertain malignant potential (≤18 years)*</td>
</tr>
<tr>
<td>Sarcoma (consider the Soft Tissue protocol)</td>
</tr>
<tr>
<td>Lymphoma (consider the Hodgkin or non-Hodgkin Lymphoma protocols)</td>
</tr>
</tbody>
</table>

*This protocol applies ONLY to adrenal carcinomas in all age groups. Pediatric adrenal cortical tumors (≤18 years) have different diagnostic criteria for malignancy and are, in general, treated under protocols that may differ significantly from the recommendations for adult-type tumors.

With guidance from the CAP Cancer and CAP Pathology Electronic Reporting Committees.

* Denotes primary author.
Accreditation Requirements
This protocol can be utilized for a variety of procedures and tumor types for clinical care purposes. For accreditation purposes, only the definitive primary cancer resection specimen is required to have the core and conditional data elements reported in a synoptic format.

- **Core data elements** are required in reports to adequately describe appropriate malignancies. For accreditation purposes, essential data elements must be reported in all instances, even if the response is “not applicable” or “cannot be determined.”
- **Conditional data elements** are only required to be reported if applicable as delineated in the protocol. For instance, the total number of lymph nodes examined must be reported, but only if nodes are present in the specimen.
- **Optional data elements** are identified with “+” and although not required for CAP accreditation purposes, may be considered for reporting as determined by local practice standards.

The use of this protocol is not required for recurrent tumors or for metastatic tumors that are resected at a different time than the primary tumor. Use of this protocol is also not required for pathology reviews performed at a second institution (ie, secondary consultation, second opinion, or review of outside case at second institution).

Synoptic Reporting
All core and conditionally required data elements outlined on the surgical case summary from this cancer protocol must be displayed in synoptic report format. Synoptic format is defined as:

- Data element: followed by its answer (response), outline format without the paired Data element: Response format is NOT considered synoptic.
- The data element should be represented in the report as it is listed in the case summary. The response for any data element may be modified from those listed in the case summary, including “Cannot be determined” if appropriate.
- Each diagnostic parameter pair (Data element: Response) is listed on a separate line or in a tabular format to achieve visual separation. The following exceptions are allowed to be listed on one line:
  - Anatomic site or specimen, laterality, and procedure
  - Pathologic Stage Classification (pTNM) elements
  - Negative margins, as long as all negative margins are specifically enumerated where applicable
- The synoptic portion of the report can appear in the diagnosis section of the pathology report, at the end of the report or in a separate section, but all Data element: Responses must be listed together in one location

Organizations and pathologists may choose to list the required elements in any order, use additional methods in order to enhance or achieve visual separation, or add optional items within the synoptic report. The report may have required elements in a summary format elsewhere in the report IN ADDITION TO but not as replacement for the synoptic report ie, all required elements must be in the synoptic portion of the report in the format defined above.

Summary of Changes

v 4.2.0.0

- General Reformatting
- Revised Margins Section
- Revised Lymph Nodes Section
- Added Distant Metastasis Section
- Removed pTX and pNX Staging Classification
Reporting Template

Protocol Posting Date: June 2021
Select a single response unless otherwise indicated.

CASE SUMMARY: (ADRENAL GLAND)
Standard(s): AJCC-UICC 8

# This protocol applies to adrenal cortical carcinomas in all age groups. Pediatric adrenal cortical tumors (18 years old or younger) have different diagnostic criteria for malignancy and are, in general, treated under protocols that may differ significantly from the recommendations for adult-type tumors.

CLINICAL

+Patient Age Group
   ___ Adult (older than 18 years)
   ___ Pediatric (18 years old or younger)

+Clinical History (specify): _________________

+Functional Status (Notes A, B) (select all that apply)
   ___ Urinary 17-ketosteroids increased (10 mg / g creatinine / 24 hours)
   ___ Cushing syndrome
   ___ Conn syndrome
   ___ Virilization
   ___ Feminization
   ___ Weight loss
   ___ Other (specify): _________________

SPECIMEN

Procedure
   ___ Percutaneous needle biopsy
   ___ Endoscopic directed biopsy (specify radiographic technique): _________________
   ___ Adrenalectomy, total
   ___ Adrenalectomy, partial
   ___ Other (specify): _________________
   ___ Not specified

Specimen Laterality
   ___ Right
   ___ Left
   ___ Bilateral
   ___ Other (specify): _________________
   ___ Not specified

TUMOR

Histologic Type (Notes C, D)
   ___ Adrenal cortical carcinoma
___ Adrenal cortical carcinoma, oncocytic type
___ Adrenal cortical carcinoma, myxoid type
___ Adrenal cortical carcinoma, sarcomatoid type
___ Other histologic type not listed (specify): ____________________
___ Carcinoma, type cannot be determined: ____________________

+Histologic Type Comment: ____________________

Histologic Grade (required for adult patients only) (Notes C,D)
___ Not applicable
___ Low grade (less than or equal to 20 mitoses per 50 high-power fields)
___ High grade (greater than 20 mitoses per 50 high-power fields)

# Generally due to core needle biopsy, with insufficient viable tumor to count 50 HPFs.
___ Cannot be assessed (explain)#: ____________________

Tumor Size (Note E,F)
___ Greatest dimension in Centimeters (cm): __________ cm

+Additional Dimension in Centimeters (cm): ____ x ____ cm
___ Cannot be determined (explain): ____________________

Tumor Weight (Note G)
___ Specify weight (g): ________________ g
___ Other (specify): ____________________
___ Cannot be determined: ____________________

Site(s) Involved by Direct Tumor Extension (select all that apply)
___ Confined to adrenal cortex without invasion through tumor capsule (if present)
___ Invades into or through the adrenal capsule
___ Kidney
___ Pancreas
___ Liver
___ Spleen
___ Diaphragm
___ Stomach
___ Other adjacent organs and structures (specify): ____________________
___ Cannot be determined: ____________________
___ Not applicable (no evidence of primary tumor)

Lymphovascular Invasion (Note H) (select all that apply)
___ Not identified
___ Large vessel invasion, renal vein (including when identified clinically)
___ Large vessel invasion, vena cava (including when identified clinically)
___ Large vessel invasion, not otherwise specified
___ Microscopic angioinvasion
___ Lymphatic invasion
___ Cannot be determined: ____________________

+Tumor Description (select all that apply)
___ Hemorrhagic
___ Necrotic
Other (specify): _________________

+Tumor Comment: _________________

**MARGINS**

**Margin Status**
___ All margins negative for carcinoma

**Closest Margin(s) to Carcinoma**
___ Specify closest margin(s): _________________
___ Cannot be determined (explain): _________________

+Distance from Carcinoma to Closest Margin
Specify in Millimeters (mm)
___ Exact distance: _________________ mm
___ At least: _________________ mm
___ Less than 1 mm
___ Other (specify): _________________
___ Cannot be determined (explain): _________________

___ Carcinoma present at margin

**Margin(s) Involved by Carcinoma**
___ Specify involved margin(s): _________________
___ Cannot be determined (explain): _________________
___ Other (specify): _________________
___ Cannot be determined (explain): _________________

+Margin Comment: _________________

**REGIONAL LYMPH NODES**

**Regional Lymph Node Status**
___ Not applicable (no regional lymph nodes submitted or found)
___ Regional lymph nodes present
___ All regional lymph nodes negative for tumor
___ Tumor present in regional lymph node(s)

**Number of Lymph Nodes with Tumor**
___ Exact number (specify): _________________
___ At least (specify): _________________
___ Other (specify): _________________
___ Cannot be determined (explain): _________________

+Extranodal Extension
___ Not identified
___ Present
___ Cannot be determined: _________________
___ Other (specify): _________________
___ Cannot be determined (explain): _________________

**Number of Lymph Nodes Examined**
___ Exact number (specify): _________________
___ At least (specify): _________________
___ Other (specify): _________________
___ Cannot be determined (explain): __________________________

+Regional Lymph Node Comment: ____________________

DISTANT METASTASIS

Distant Site(s) Involved, if applicable (select all that apply)
___ Not applicable
___ Liver: ______________________________
___ Lung: ______________________________
___ Other (specify): ______________________
___ Cannot be determined: __________________

PATHOLOGIC STAGE CLASSIFICATION (pTNM, AJCC 8th Edition) (Note 1)

Reporting of pT, pN, and (when applicable) pM categories is based on information available to the pathologist at the time the report is issued. As per the AJCC (Chapter 1, 8th Ed.) it is the managing physician's responsibility to establish the final pathologic stage based upon all pertinent information, including but potentially not limited to this pathology report.

TNM Descriptors (select all that apply)
___ Not applicable
___ m (multiple primary tumors)
___ r (recurrent)
___ y (post-treatment)

pT Category
There is no category of carcinoma in situ (pTis) relative to carcinomas of the adrenal gland.
___ pT not assigned (cannot be determined based on available pathological information)
___ pT0: No evidence of primary tumor
___ pT1: Tumor less than or equal to 5 cm in greatest dimension, no extra-adrenal invasion
___ pT2: Tumor greater than 5 cm, no extra-adrenal invasion
___ pT3: Tumor of any size with local invasion, but not invading adjacent organs
___ pT4: Tumor of any size with invasion of adjacent organs (kidney, diaphragm, pancreas, spleen, or liver) or large blood vessels (renal vein or vena cava)

pN Category (Note J)
___ pN not assigned (no nodes submitted or found)
___ pN not assigned (cannot be determined based on available pathological information)
___ pN0: No regional lymph node metastasis
___ pN1: Metastasis in regional lymph node(s)

pM Category (required only if confirmed pathologically) (Note K)
___ Not applicable - pM cannot be determined from the submitted specimen(s)
___ pM1: Distant metastasis

ADDITIONAL FINDINGS

+Additional Findings (select all that apply)
___ None identified
___ Hemorrhage
___ Cystic change
___ Calcifications
___ Other (specify): _________________

SPECIAL STUDIES (Note L)

+Ki-67 Labeling Index
___ Specify percentage: ____________________%
___ Other (specify): _________________

+Reticulin Stain Results (specify type(s) and result(s)): _________________

+Other Ancillary Study Findings (specify types and results): _________________

COMMENTS

Comment(s): _________________
Explanatory Notes

A. Relevant History
Endocrine manifestations, such as hypertension, change in body habitus, feminization, or virilism, are important, as is the knowledge of whether the patient suffers from an adrenal-related disease or syndrome (eg, Cushing disease, Conn syndrome).

Also of import are family history, previous surgery for adrenal tumors (both benign and malignant) or other endocrine organs, other tumors that may metastasize to the adrenal gland, and endocrine or other therapies. In addition, while the majority of adrenal cortical carcinomas occur sporadically, occasionally adrenal cortical carcinoma may be associated with hereditary cancer syndromes. Such hereditary cancer syndromes include but not limited to Li-Fraumeni syndrome or SBLA (sarcoma; breast and brain tumors; leukemia, laryngeal carcinoma and lung cancer; and adrenal cortical carcinoma) syndrome, Beckwith-Wiedemann syndrome, and Lynch syndrome.

References

B. Endocrine Status
Laboratory findings are important in the evaluation of an adrenal mass. Tumors that are functional, ie, secrete cortisol, aldosterone, or sex hormones, tend to be discovered at an earlier stage than nonfunctional tumors. Virilizing tumors are more frequently identified as carcinomas than adenomas in adult age groups. Nonfunctional tumors come to attention due to mass effect and are usually larger. Adrenal cortical neoplasms that secrete glucocorticoids can also be diagnosed by pathologists by checking the status of the non-tumorous adrenal cortex. In the absence of exogenous cortisol administration, the presence of atrophy in the non-tumorous cortex should prompt the attention of the pathologist to the possibility of glucocorticoid-secreting adrenal cortical neoplasm. This issue is of clinical significance especially in patients with subclinical Cushing syndrome as affected patients may develop Addisonian crisis if postoperative cortisol replacement is not considered. Therefore, the thickness of the nontumorous cortex should be checked in all adrenalectomy specimens. In addition, careful evaluation of the non-tumorous cortex may help to identify underlying pathologies like PPNAD (primary pigmented nodular adrenal cortical disease).

Evidence also suggests that functional adrenal cortical carcinomas are biologically more aggressive than non-functional carcinomas.

References

C. Histologic Type
The following histologic classification of adrenal tumors is from the World Health Organization (WHO) classification of tumors of the adrenal gland. Thus, this protocol applies only to adrenal cortical carcinoma and does not apply to other tumor types.

References

D. Histologic Grade
Adrenal cortical carcinomas are not usually graded on histologic grounds. Severe nuclear atypia, high mitotic count, vascular invasion, tumor necrosis, and other microscopic features may, in combination, support a diagnosis of adrenal cortical carcinoma and should be recorded. When several histologic features are present together (eg, highly atypical nuclei, necrosis, vascular invasion, increased mitotic activity, and atypical mitoses), the risk of distant metastases is increased. In some studies, specific combinations of features, such as mitotic rates of >5 per 50 high-power fields (HPF) along with atypical mitosis and venous invasion, have been found to correlate with metastasis or recurrence of adult adrenal cortical carcinomas.

Mitotic index has been identified as a prognostic factor that is independently predictive of behavior, with low- and high-grade categories applied based on ≤20 mitoses/50 HPF and >20 mitoses/50 HPF. While the concept of mitotic tumor grade is often used in adult adrenal cortical carcinomas, the optimal cut-off for pediatric adrenal cortical cancers remains to be validated in large clinical series. Nevertheless, documentation of this finding in pediatric age group tumors is recommended. Other scoring systems are suggested that are able to predict metastatic potential, with 3 x mitotic rate (>5/50 HPF) + 5 x presence of necrosis + proliferation index in the most proliferative areas. Further, Ki-67 has been found to show a superior performance of estimating proliferative rate compared to mitotic count in hematoxylin-eosin sections, suggested to be a better prognostic indicator in overall patient survival. Finally, a reticulin algorithm has been recommended to assess change in reticulin pattern of staining based on necrosis, high mitotic rate, and vascular invasion.

The criteria used in adults to separate benign from malignant cortical tumors are not entirely applicable to adrenocortical tumors in pediatric age groups. Further, pediatric adrenocortical neoplasms showing histologic features worrisome for malignancy in adults (eg, capsular invasion, vascular invasion, increased mitotic activity, atypical mitoses, necrosis) may not be predictive of biologic behavior; such a pediatric adrenocortical neoplasm exhibiting such histologic features may have a clinically benign course. A number of classification schemes attempting to separate benign from malignant pediatric adrenocortical tumors have been proposed. One of these studies is based on the presence (carcinoma) or absence (adenoma) of 4 histologic features (modified Weiss system) including high nuclear grade, necrosis, mitotic rate greater than 5 per 50 HPF, and atypical mitoses; another study found that tumor weight was the only reliable predictor of behavior, with tumors weighing over 500 g being malignant; and another study correlated tumor volume of greater than 200 cm³ and weight greater than 80 g associated with an adverse outcome. Subsequent to these studies, Wieneke et al. proposed classifying pediatric adrenocortical neoplasms based on a series of 9 criteria including tumor weight greater than 400 g, tumor size greater
than 10.5 cm, extension into periadrenal soft tissues and/or adjacent organs, invasion into the vena cava, venous invasion, capsular invasion, presence of tumor necrosis, mitotic rate greater than 15 per 20 HPF, and the presence of atypical mitoses. Based on this study, the presence of up to 2 of these criteria was associated with a benign outcome, 3 criteria were considered indeterminate for malignancy, and 4 or more criteria were associated with malignant behavior. A recent series also underscored that the Wieneke multiparameter scoring system can accurately predict the clinical course of childhood adrenal cortical tumors.

The Lin-Weiss-Bisceglia criteria are applied to oncocytic adrenocortical tumors. The identification of one of the three major criteria (vascular invasion, atypical mitosis, and mitotic activity greater than 5 per 50 HPF) supports the diagnosis of oncocytic adrenocortical carcinoma, whereas the presence of any minor criteria (large tumor size greater than 10 cm and/or tumor weight greater than 200 gram, necrosis, capsular invasion and sinusoidal invasion) warrants the diagnosis of an oncocytic adrenocortical tumor of uncertain malignant potential. The diagnosis of an oncocytic adrenocortical adenoma requires absence of all major and minor criteria.

**E. Adrenal Incidentalomas**

With the technical advancement and availability of radiographic imaging, many asymptomatic adrenal neoplasms are coming to clinical attention at much smaller limits. Such asymptomatic neoplasms are referred to as “adrenal incidentalomas.” Adrenal incidentalomas can present clinical dilemmas to the treating physician. A consensus statement on how to manage adrenal incidentalomas was proposed in 2002. Follow-up and treatment decisions are based on a combination of clinical/laboratory/radiologic parameters and tumor size (<4 cm, 4-6 cm, >6 cm).

**References**

**F. Primary Site and Laparoscopic Surgery**

The adrenal glands sit in a supra-renal location (retroperitoneal) surrounded by connective tissue and a layer of adipose tissue. The adrenal glands are intimately associated with the kidneys and are enclosed within the renal fascia (Gerota’s). Each gland has an outer cortex, which is lipid rich and on gross examination appears bright yellow, surrounding an inner “gray-white” medullary compartment composed of chromaffin cells. There is a rich vascular supply derived from the aorta, inferior phrenic arteries, and renal arteries. Veins emerge from the hilum of the glands. The shorter right central vein opens into the inferior vena cava, and the left central vein opens into the renal vein. A single adrenal vein is present for each gland. The regional lymph nodes include the aortic lymph nodes (para-aortic, peri-aortic) and retroperitoneal lymph nodes.

An entire adrenal tumor may be removed laparoscopically, but with this technique, the gland may become fragmented. This anatomic information, including maximal diameter of the resected tumor, should be provided by the surgeon. A recent study demonstrates a tumor size greater than 6.5 cm is likely to be malignant in adult adrenocortical neoplasms. However, the Wienke scoring scheme that is used to assess the pediatric adrenocortical neoplasms consider a tumor size greater than 10.5 cm as a risk factor.

**References**

**G. Weight**

Accurate weights of adrenal cortical neoplasms are important. Although tumor mass cannot be used as the sole criterion for malignancy, adrenal cortical neoplasms weighing less than 50 g are often benign, whereas the weight of malignant tumors is usually greater than 100 g in adults. Wienke et al. reported that the mean tumor weight of pediatric adrenal cortical carcinomas was 631 g (range 24–2260 g). The Wienke scoring system uses the adrenal cortical tumor weight greater than 400 g as a risk modifier in pediatric age groups. Weight is a reflection of gland weight rather than tumor weight because, in actuality, following surgically excision, the tumor is not dissected from the gland proper and weighed separately.
H. Lymphovascular Invasion
According to the Weiss classification, which is typically used in the diagnostic workup of adult conventional adrenal cortical neoplasms, distinguishing between large vessel (venous) and small vessel (capillary/lymphatic) invasion may have an impact on prognosis, with large-caliber vascular space invasion portending a worse prognosis. A recent adult series also showed that microscopic angioinvasion (venous invasion) defined as tumor cells invading through a vessel wall and intravascular tumor cells admixed with thrombus proved to be the best prognostic parameter, predicting adverse outcome in all adrenal cortical carcinomas as well as within low-grade adrenal cortical carcinomas. These findings underscore the importance of the identification of angioinvasion in these neoplasms.

I. Staging
There are several staging systems, including those proposed by MacFarlane and modified by Sullivan et al and Henley et al and the European Network for the Study of Adrenal Tumors (ENSAT) staging scheme with the American Joint Committee on Cancer (AJCC) and the International Union Against Cancer (UICC) accepting the ENSAT as part of the TNM staging system for adrenal cortical carcinoma.

References

J. Regional Lymph Nodes
Regional lymph nodes include aortic (para-aortic and peri-aortic) and retroperitoneal (peri-nephric and peri-adrenal).

K. Metastatic Sites
Common metastatic sites include liver, lung, and retroperitoneum. Metastases to brain and skin are uncommon, although cutaneous involvement of the scalp can simulate angiosarcoma.1

References

L. Ancillary Studies
Special procedures may include frozen sections, cytologic imprints, immunohistochemical stains, histochemical stains, electron microscopy, flow cytometry, molecular studies, and cytogenetic studies. For non-functional tumors, it is important to confirm the adrenal cortical origin by using appropriate biomarkers1. Accurate assessment of Ki-67 labeling index is of clinical significance in all age groups1,2,3 Ki-67 labeling index may be performed manually or via image analysis1,4,5; if the latter, specifying methodology, software,
or technique is suggested. Mismatch repair proteins may be tested, as adrenal cortical carcinoma is recognized in approximately 3% of Lynch syndrome patients.6,7
