Protocol for the Examination of Specimens From Patients With Primary Gestational Trophoblastic Malignancy

Version: 4.1.0.0
Protocol Posting Date: June 2021
CAP Laboratory Accreditation Program Protocol Required Use Date: March 2022
The changes included in this current protocol version affect accreditation requirements. The new deadline for implementing this protocol version is reflected in the above accreditation date.

For accreditation purposes, this protocol should be used for the following procedures AND tumor types:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resection</td>
<td>Includes hysterectomy with or without oophorectomy and/or salpingectomy</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Tumor Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Malignant gestational trophoblastic tumor</td>
<td>Includes invasive hydatidiform mole, choriocarcinoma, placental site trophoblastic tumor</td>
</tr>
</tbody>
</table>

This protocol is NOT required for accreditation purposes for the following:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Biopsy</td>
<td></td>
</tr>
<tr>
<td>Curettage</td>
<td></td>
</tr>
<tr>
<td>Primary resection specimen with no residual cancer (eg, following neoadjuvant therapy)</td>
<td></td>
</tr>
<tr>
<td>Cytologic specimens</td>
<td></td>
</tr>
</tbody>
</table>

The following tumor types should NOT be reported using this protocol:

<table>
<thead>
<tr>
<th>Tumor Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nongestational trophoblastic tumors (eg, ovarian choriocarcinoma)</td>
<td></td>
</tr>
<tr>
<td>Benign trophoblastic tumors (eg, placental site nodule)</td>
<td></td>
</tr>
</tbody>
</table>

Authors
Uma G. Krishnamurti, MD, PhD*; Barbara A. Crothers, DO*.

With guidance from the CAP Cancer and CAP Pathology Electronic Reporting Committees.
* Denotes primary author.
Accreditation Requirements
This protocol can be utilized for a variety of procedures and tumor types for clinical care purposes. For accreditation purposes, only the definitive primary cancer resection specimen is required to have the core and conditional data elements reported in a synoptic format.

- **Core data elements** are required in reports to adequately describe appropriate malignancies. For accreditation purposes, essential data elements must be reported in all instances, even if the response is “not applicable” or “cannot be determined.”
- **Conditional data elements** are only required to be reported if applicable as delineated in the protocol. For instance, the total number of lymph nodes examined must be reported, but only if nodes are present in the specimen.
- **Optional data elements** are identified with “+” and although not required for CAP accreditation purposes, may be considered for reporting as determined by local practice standards.

The use of this protocol is not required for recurrent tumors or for metastatic tumors that are resected at a different time than the primary tumor. Use of this protocol is also not required for pathology reviews performed at a second institution (ie, secondary consultation, second opinion, or review of outside case at second institution).

Synoptic Reporting
All core and conditionally required data elements outlined on the surgical case summary from this cancer protocol must be displayed in synoptic report format. Synoptic format is defined as:

- **Data element: followed by its answer (response), outline format without the paired Data element: Response format is NOT considered synoptic.**
- The data element should be represented in the report as it is listed in the case summary. The response for any data element may be modified from those listed in the case summary, including "Cannot be determined" if appropriate.
- Each diagnostic parameter pair (Data element: Response) is listed on a separate line or in a tabular format to achieve visual separation. The following exceptions are allowed to be listed on one line:
  - Anatomic site or specimen, laterality, and procedure
  - Pathologic Stage Classification (pTNM) elements
  - Negative margins, as long as all negative margins are specifically enumerated where applicable
- The synoptic portion of the report can appear in the diagnosis section of the pathology report, at the end of the report or in a separate section, but all Data element: Responses must be listed together in one location

Organizations and pathologists may choose to list the required elements in any order, use additional methods in order to enhance or achieve visual separation, or add optional items within the synoptic report. The report may have required elements in a summary format elsewhere in the report IN ADDITION TO but not as replacement for the synoptic report ie, all required elements must be in the synoptic portion of the report in the format defined above.

Summary of Changes
v 4.1.0.0

- General Reformatting
- Deprecated Clinical History
- Other Tissue / Organ Involvement
- Added Equivocal Response to Lymphovascular Invasion (LVI)
- Created Separate Distant Metastases Section
- Removed pTX Staging Classification

PATHOLOGIC STAGE CLASSIFICATION (pTNM, AJCC 8th Edition) (Note B)

Reporting of pT and (when applicable) pM categories is based on information available to the pathologist at the time the report is issued. As per the AJCC (Chapter 1, 8th Ed.) it is the managing physician’s responsibility to establish the final pathologic stage based upon all pertinent information, including but potentially not limited to this pathology report.

TNM Descriptors (select all that apply)
___ Not applicable: _________________
___ r (recurrent)
___ y (post-treatment)

pT Category
___ pT not assigned (cannot be determined based on available pathological information)
___ pT0: No evidence of primary tumor
___ pT1: Tumor confined to uterus
___ pT2: Tumor extends to other genital structures (ovary, tube, vagina, broad ligaments) by metastasis or direct extension

pM Category (required only if confirmed pathologically)
___ Not applicable - pM cannot be determined from the submitted specimen(s)
___ pM1: Distant metastasis
___ pM1a: Lung metastasis
___ pM1b: All other distant metastasis
___ pM1 (subcategory cannot be determined)
FIGO STAGE

+FIGO Stage (2018 FIGO Cancer Report)
   □ I: Disease confined to the uterus
   □ II: Gestational trophoblastic tumor extends outside of the uterus, but limited to the genital structures (adnexa, vagina, broad ligament)
   □ III: Gestational trophoblastic tumor extends to the lungs, with or without known genital tract involvement
   □ IV: All other metastatic sites

ADDITIONAL FINDINGS

+Additional Findings (select all that apply)
   □ None identified
   □ Implantation site

Explanatory Notes

A. Histologic Type

Previous History
Previous slides should be reviewed by the pathologist if it is deemed necessary by the gynecologist or pathologist for optimal evaluation of the specimen.

Histologic Classification
A modified World Health Organization (WHO) classification of gestational trophoblastic lesions is as follows. 1,2,3,4,5,6,7,8

Histologic Type
Exaggerated placental site, composed of seemingly increased intermediate trophoblast at the implantation site, is most commonly seen in uterine curettage specimens. These lesions are benign and do not require staging.

Invasive hydatidiform moles are complete hydatidiform moles with myometrial and/or vascular invasion. Metastatic moles are complete hydatidiform molar villi in extrauterine locations.

Gestational choriocarcinoma has a biphasic pattern, with malignant mononuclear villous cytotrophoblast and intermediate trophoblast rimmed by malignant multinucleated syncytiotrophoblast. Malignant cells show marked cytologic atypia and brisk mitotic activity. While more than 50% of choriocarcinomas are preceded by a complete mole, other cases are preceded by spontaneous or induced abortion (25%), normal pregnancy (22.5%), or ectopic pregnancy (2.5%). Most cases of intraplacental choriocarcinoma are diagnosed in the third trimester or postpartum, although they can occur in any trimester. Intramolar or early choriocarcinoma can coexist with complete or invasive mole. The molar villi are surrounded by a markedly atypical trophoblastic proliferation with a focally biphasic pattern resembling that of choriocarcinoma.

Placental site nodules are of benign intermediate trophoblastic origin. These lesions are generally benign and do not require staging. However, placental site nodules have been described in association with epithelioid trophoblastic tumors (ETT). Furthermore, there is a morphological continuum, and atypical placental site nodules present with equivocal morphological features, being larger and showing greater cellularity than is typically seen in a placental site nodule, but having insufficient features for a diagnosis of epithelioid trophoblastic tumor. Cyclin E is useful in the distinction of placental site nodule and epithelioid trophoblastic tumor, with the former showing focal weak nuclear staining, whereas the latter typically shows diffuse (>50% of tumor nuclei) intense staining. Atypical placental site nodules may show elevated cyclin E staining. Epithelioid trophoblastic tumor presents usually as a nodular lesion with destructive growth, consisting of epithelioid intermediate trophoblastic cells. In difficult cases, a Ki-67 proliferation index of > 10% is important for diagnosis. PDL1 is highly expressed in ETT.

Placental site trophoblastic tumor (PSTT) is a malignant tumor of implantation site intermediate trophoblast. Most tumors have a low mitotic count, with 1–2 mitoses/mm² (2–4 mitoses/10 HPF of 0.5 mm in diameter and 0.2 mm² in area). Vascular invasion in which the tumor cells replace the vascular wall of myometrial vessels is often present. Ki-67 is expressed in 10–30% of cells.

Composite or mixed trophoblastic lesions are recognized. Epithelioid trophoblastic tumors have been described coexistent with placental site nodule and with placental site trophoblastic tumor and
choriocarcinoma either alone or in combination. Rather than specifying the “Histologic Type” as “Unclassified,” we would recommend classifying composite lesions as “Other,” with further annotation of the different components.

**Immunohistochemistry in Diagnosis of Gestational Trophoblastic Disease**

**Immunohistochemistry in the Distinction of, Placental Site Nodule, Placental Site Trophoblastic Tumor, Epithelioid Trophoblastic Tumor, and Choriocarcinoma.**

Kurman and Shih have dissected subpopulations of trophoblast that give rise to trophoblast tumors and tumor-like lesions. It is proposed that exaggerated placental site and placental site trophoblastic tumor arise from implantation site intermediate trophoblast, whereas placental site nodule and epithelioid trophoblastic tumor arise from chorionic-type intermediate trophoblast. Diffuse and intense immunoreactivity for both HSD3B1 (Hydroxyl-δ-5-steroid dehydrogenase) and low-molecular weight cytokeratin suggests a neoplasm of trophoblastic origin. A panel of immunohistochemical stains (Tables 1) is recommended to distinguish these entities.

Adapted from Kalhor N et al.\(^5\) The percentages refer to the number of cases expressing the marker. Pan-K, Pankeratin (AE1AE3); CEA, carcinoembryonic antigen.
Additional Notes on Table 2

CD10: variable expression in ITTs and choriocarcinoma: 1% to 100% of cells staining.

p16: Cervical carcinomas showed diffuse nuclear staining for this marker. About half the ITTs had variable staining (1% to 75% of cells), mainly cytoplasmic.

CK5/6: All cervical carcinomas were positive, staining 26% to 100% of cells. Two cases of ITT were focally positive (<25% of cells).

A review by Wells M has highlighted the most common diagnostic errors in trophoblastic lesions:
1. Misinterpretation of early complete hydatidiform mole as partial mole.
2. Over diagnosis of hydatidiform mole in tubal pregnancy because of florid appearance of normal early first-trimester trophoblastic proliferation.
3. Misdiagnosis of exuberant placental site nonvillus trophoblast as placental site trophoblastic tumor or choriocarcinoma.
4. Misdiagnosis of nonvillus trophoblast, often seen in the context of complete hydatidiform mole, as choriocarcinoma or placental site trophoblastic tumor.

References

B. Pathologic Stage Classification
The 8th edition of the TNM staging system of the American Joint Committee on Cancer (AJCC) and the International Union Against Cancer (UICC)1 and the corresponding updated staging system of the International Federation of Gynecology and Obstetrics (FIGO)2, are recommended, as shown below. Both are based not only on the anatomic extent of the tumor, but on additional factors, including clinical and laboratory findings.

According to AJCC/UICC convention, the designation “T” refers to a primary tumor that has not been previously treated. The symbol “p” refers to the pathologic classification of the TNM, as opposed to the clinical classification, and is based on gross and microscopic examination. pT entails a resection of the
primary tumor or biopsy adequate to evaluate the highest pT category, and pM implies microscopic examination of distant lesions. Clinical classification (cTNM) is usually carried out by the referring physician before treatment during initial evaluation of the patient or when pathologic classification is not possible. Gestational trophoblastic tumors do not have an N classification (see below).

Pathologic staging is usually performed after surgical resection of the primary tumor. Pathologic staging depends on pathologic documentation of the anatomic extent of disease, whether or not the primary tumor has been completely removed. If a biopsied tumor is not resected for any reason (eg, when technically infeasible) and if the highest T category or the M1 category of the tumor can be confirmed microscopically, the criteria for pathologic classification and staging have been satisfied without total removal of the primary cancer.

**TNM Descriptors**
For identification of special cases of TNM or pTNM classifications, the "y," "r," and "a" prefixes are used. Although they do not affect the stage grouping, they indicate cases needing separate analysis.

The "y" prefix indicates those cases in which classification is performed during or after initial multimodality therapy (ie, neoadjuvant chemotherapy, radiation therapy, or both chemotherapy and radiation therapy). The cTNM or pTNM category is identified by a "y" prefix. The ycTNM or ypTNM categorizes the extent of tumor actually present at the time of that examination. The "y" categorization is not an estimate of tumor before multimodality therapy (ie, before initiation of neoadjuvant therapy).

The "r" prefix indicates a recurrent tumor when staged after a documented disease-free interval and is identified by the "r" prefix: rTNM.

The "a" prefix designates the stage determined at autopsy: aTNM.

**Additional Descriptors**

**Residual Tumor (R)**
Tumor remaining in a patient after therapy with curative intent (eg, surgical resection for cure) is categorized by a system known as R classification, shown below.

RX Presence of residual tumor cannot be assessed
R0 No residual tumor
R1 Microscopic residual tumor
R2 Macroscopic residual tumor

For the surgeon, the R classification may be useful to indicate the known or assumed status of the completeness of a surgical excision. For the pathologist, the R classification is relevant to the status of the margins of a surgical resection specimen. That is, tumor involving the resection margin on pathologic examination may be assumed to correspond to residual tumor in the patient and may be classified as macroscopic or microscopic according to the findings at the specimen margin(s).

**T Category Considerations**

**Lymphovascular Invasion**
Lymphovascular invasion (LVI) indicates whether microscopic lymphovascular invasion is identified. LVI includes lymphatic invasion, vascular invasion, or lymphovascular invasion. According to AJCC/UICC convention, LVI does not affect the T category indicating local extent of tumor unless specifically included in the definition of a T category. At times, it may be difficult to evaluate a specimen for vascular/lymphatic vessel invasion, as in cases with crush artifact or suboptimal fixation. In these cases, it can be
categorized as “cannot be determined”. At other times, it may be difficult to be definitive whether vascular/lymphatic vessel invasion is present. This can include cases where retraction artifact or artifactual transfer of tumor cells is a consideration. In other cases, foci may be suspicious but not definitive for invasion. All of these situations can be categorized as “equivocal for invasion”. In cases where one cannot be definitive, a qualifying note explaining the interpretive difficulty and the extent of possible involvement is recommended, since it may help to direct medical management.

**N Category Considerations**
There is no regional nodal designation (N classification) in the staging of gestational trophoblastic tumors. Nodal involvement in these tumors is rare but has an extremely poor prognosis. Nodal metastases should be classified as metastatic M1b disease.

**M Category Considerations**
Genital metastasis (vagina, broad ligament, ovary, fallopian tube) is classified as T2. Direct invasion or metastasis to any nongenital structure is classified using the M classification.

The score on the FIGO-modified World Health Organization (WHO) Prognostic Scoring Index given below is used to stratify women with gestational trophoblastic neoplasia in addition to the stage group. The risk score is appended to the anatomic FIGO stage. The current FIGO classification includes an anatomic stage designated by Roman numeral I, II, III, or IV, followed by the risk factor score expressed in Arabic numerals (e.g., stage II: 4, stage IV: 9). The risk score includes factors that are not anatomic pathology. It is best assigned by the treating clinician and is not a required element in the CAP protocol.

*The T and M categories are defined to correspond to the FIGO stages.*

In summary, the following factors should be considered and noted in reporting:

1. Prior chemotherapy for known gestational trophoblastic tumors should be reported.
2. Benign placental site lesions (exaggerated placental site and placental site nodule) should be reported separately and are not staged.
3. Histologic verification of disease is not required when the HCG is abnormally elevated.
4. TNM and FIGO staging applies to choriocarcinoma, invasive hydatidiform mole, placental site trophoblastic tumor, and epithelioid trophoblastic tumor.
5. In contrast to other sites, an N classification (regional lymph node status) does not apply to gestational trophoblastic tumors. Any lymph node metastasis should be classified as metastatic (M1b) disease.
